Use multiple git account:

I sort of got confused at the beginning when I tried to use multiple github accounts. This is actually practical: you might use different git account when working different projects.

The problem is I've already setup a global user account. When I cloned repos from my other github accounts, every time I tried to push local editing to remote, "permission denied" shows up. Essentially, it's because of the global setting.

One of the simple way to resolve this is with three lines of commands:

First replace user information:

git config --replace-all user.email desired_email_address
git config --replace-all user.name desired_username

Second, you want replace the remote origin using desired username
git remote set-url origin https://desired_username@github.com/desired_username/repo
